Abstract

Blackberry leaves have been used as a tea substitute in many herbal mixtures. Medicinal properties of this plant material are related to a high level of components with antioxidant activity, such as phenolic compounds. The aim of the research was to evaluate the effect of different extraction conditions on the content of phenolic compounds and antioxidant activity of blackberry leaves extracts. In this study, blackberry leaves extracts were produced by an aqueous extraction procedure. Different extraction conditions: water temperature (40 and 80 °C) and extraction time (15 and 30 min) were investigated. The blackberry leaves extract prepared by applying higher temperature (80 °C) and longer time (30 minutes) was characterized by the highest contents of total phenolic compounds (1534.15 mg gallic acid equivalents L-1), flavonoids (715 mg quercetin equivalents L-1) and flavan-3-ols (28.21 mg (+)-catechin L-1). Also, this extract expressed the highest antioxidant activity in terms of the ferric reducing ability of plasma (27.33 mmol Trolox equivalents L-1) and generation of 2,2′-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) radical cation (1.47 mmol Trolox equivalents L-1). The obtained results indicated that the produced extracts are a rich source of phenolic compounds with high antioxidant activity. Among investigated conditions, the use of water heated to higher temperature (80 °C) during prolonged time (30 min) is the most optimal procedure for the extraction of phenolic compounds with antioxidant activity from blackberry leaves. Further research is needed to determine the exact phenolic profile and their bioavailability, as well as to develop new functional food ingredients or nutraceuticals containing blackberry leaves extracts.

Keywords: blackberry leaves, phenolic compounds, antioxidant activity, flavonoids, flavan-3-ols.

Introduction

The use of herbal remedies is widespread among different patient groups and in the general population to promote health (Holst et al, 2009). The trend of wide using and applications of herbs as herbal infusions or tea, as the common name, is preserved from traditional medicinal system to this day owing to the rich and diverse phytochemicals composition (Komes et al., 2014). The investigation of unconventional raw materials for tea preparation has gained particular interest (Melkadze et al., 2008). Blackberry (Rubus fruticosus L.) is widely grown and processed due to its fruits with pleasant organoleptic characteristics and a high content of compounds with health beneficial effects (Mikulic-Petkovsek et al., 2017). In addition to fruits, blackberry leaves represent a rich complex of biologically active substances (Nikitina et al., 2000). Blackberry leaves have been used as a tea substitute or constituent of herbal mixtures for many therapeutic purposes (Melkadze et al., 2008). Namely, tea made from the blackberry leaves has been used in folk medicine for their anti-inflammatory, antiviral and antimicrobial properties, as well as antiproliferative activity (Martini et al., 2009).

Health beneficial effects are mainly attributed to phenolic compounds (Nile, Park, 2014). Furthermore, sensory properties of tea, such as taste and smell, depend on the composition and content of phenolic compounds in the raw material and the degree of their changes during tea preparation (Melkadze et al., 2008).

Blackberry leaves are known to contain high content of phenolic compounds such as ellagic acid, quercetin, kaempferol, rutin, procyanidins, (+)-catechin, caffeic acid, as well as their derivatives such as ellagitannins and quercetin 3-O-β-d-glukopyranoside (Buricova et al., 2011; Gudej, Tomczyk 2004; Martini et al., 2009, Oszmiański et al., 2015, Pavlović et al., 2016). Phenolic compounds, depending on the quantitative and qualitative composition, contribute to a high antioxidant activity of blackberry leaves (Wang, Lin, 2000). The ability to subdue free radicals contributes to an important role of phenolic compounds in the prevention or delay of cancer, heart diseases and diseases of the aging process (Nile, Park, 2014). Therefore, these phytochemicals offer numerous opportunities to be used as health beneficial agents for development of new functional food products (Nile, Park, 2014). Additionally, blackberry leaves contain significant amounts of triterpenes, mineral salts and vitamin C (Gudej, Tomczyk, 2004).

Due to the potential health beneficial effects related to tea drinking, it is important to determine the optimal extraction conditions to obtain tea with high content of biologically active compounds and strong antioxidant activity. Therefore, the aim of this study was to evaluate the effect of different extraction conditions (water temperature and extraction time) on the content of phenolic compounds and antioxidant activity of blackberry leaves extracts.

Materials and Methods

Chemicals and Materials

All the chemicals used in this study were of analytical grade and used as such without further purification. Folin-Ciocalteu reagent and gallic acid were purchased from Merck (Darmstadt, Germany). Sodium carbonate, sodium nitrite, sodium dihydrogen phosphate, disodium hydrogen phosphate, sodium acetate, iron (III) chloride and aluminium chloride were supplied by Centrohem.
Sample preparation
Harvested leaves were air-dried at room temperature in dark. Moisture content was determined (92.3%) according to a method approved by AOAC (Association of Official Analytical Chemists) International (AOAC, 1997). Afterwards, the dried material was ground in a laboratory mill to fine powder.

The aqueous extraction procedure was applied. The blackberry leaves (0.5 g) were extracted in 50 mL of distilled water on a magnetic stirrer. The effect of different extraction conditions: water temperature (40 and 80 °C) and extraction time (15 and 30 min) on the content of phenolic compounds, as well as antioxidant activity of extracts was studied. After extraction, the samples were centrifuged (centrifuge model: Boeco U-320 Hamburg, Germany) at 6000 rpm during 4 minutes.

Determination of total phenolic content (TPC)
TPC was determined according to a method with Folin-Ciocalteu's reagent (Singleton, Rossi, 1965). An aliquot of each extract (0.5 mL) was mixed with 10-fold diluted Folin-Ciocalteu's phenol reagent (2.5 mL) and allowed to react for 5 minutes. The sodium carbonate solution (75 g L\(^{-1}\), 2 mL) was added to the mixture and shaken. After 2 h at reaction at room temperature, the absorbance of blue coloration was measured at 760 nm. Gallic acid was used as the standard and the results were expressed as mg gallic acid equivalents (GAE) L\(^{-1}\).

Determination of flavonoids content (TFC)
TFC was assessed spectrophotometrically according to a previously published method with some modifications (Zhishen et al., 1999). The volume of 2.5 mL of extracts was mixed with 150 μL 5% NaNO\(_2\) solution and allowed to react during 6 minutes. 10% AlCl\(_3\) (150 μL) was added and left to react for 5 minutes. Afterwards, 1 mL of 1 mol L\(^{-1}\) NaOH solution and 1.2 mL of distilled water were added and absorbance was measured at 510 nm. Quercetin was used as the standard and the results were expressed as mg quercetin equivalents (QE) L\(^{-1}\).

Determination of flavan-3-ols content
The content of flavan-3-ols was estimated using the vanillin assay (Di Stefano et al., 1989). 500 μL of each extract was mixed with 3 mL of 4% vanillin solution and allowed to react for 5 minutes. 35% chloric acid (1.5 mL) was added to mixture and vigorously shaken. After 15 minutes of reaction at room temperature in dark, the absorbance of red coloration was measured at 500 nm. The amount of flavan-3-ols was calculated according to the corresponding formula based on difference between absorbance of vanillin-containing sample and blank. The results were expressed as mg (+)-catechin equivalents (CE) L\(^{-1}\).

Determination of DPPH radical-scavenging activity
The samples were analysed according to the slightly modified previously published procedure (Sharma, Bhat, 2009). An aliquot of each extract (0.2 mL) was mixed with 2.8 mL of DPPH (2,2-diphenyl-1-picrylhydrazyl) solution (mixture of 1.86×10\(^{-4}\) mol L\(^{-1}\) DPPH in ethanol and 0.1 mol L\(^{-1}\) acetate buffer (pH 4.3) in volume ratio 2:1). Free radical scavenging activity was determined by measuring the absorbance of solution at 525 nm after 30 minutes of reaction at room temperature in dark. Trolox was used as standard and the results were expressed as mmol Trolox equivalents (TE) L\(^{-1}\).

Determination of ferric reducing/antioxidant power (FRAP assay)
The FRAP assay was carried out according to the published procedure with some modifications (Benzie, Strain, 1996). The FRAP solution was prepared by mixing acetic buffer (pH 3.6), TPTZ (2,4,6-tri(2-pyridyl)-s-triazine) (10 mmol L\(^{-1}\)), ABTS (2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid)), potassium persulfate, sodium hydroxide, quercetin and vanillin were provided by Aldrich (Sigma-Aldrich Chemie Steinheim, Germany). Ethanol was procured from Vrenje Spiritana (Belgrade, Serbia).

Blackberry leaves (Čačanska Bestrna variety) were collected in Arilje (Western Serbia) during the full ripening stage of the fruits (July, 2015). Fully ripened blackberry leaves were healthy, uniform in the size and at the same senescence stage.

Harvested leaves were air-dried at room temperature in dark. Moisture content was determined (92.3%) according to a method approved by AOAC (Association of Official Analytical Chemists) International (AOAC, 1997). Afterwards, the dried material was ground in a laboratory mill to fine powder.

The aqueous extraction procedure was applied. The blackberry leaves (0.5 g) were extracted in 50 mL of distilled water on a magnetic stirrer. The effect of different extraction conditions: water temperature (40 and 80 °C) and extraction time (15 and 30 min) on the content of phenolic compounds, as well as antioxidant activity of extracts was studied. After extraction, the samples were centrifuged (centrifuge model: Boeco U-320 Hamburg, Germany) at 6000 rpm during 4 minutes.

Determination of total phenolic content (TPC)
TPC was determined according to a method with Folin-Ciocalteu's reagent (Singleton, Rossi, 1965). An aliquot of each extract (0.5 mL) was mixed with 10-fold diluted Folin-Ciocalteu's phenol reagent (2.5 mL) and allowed to react for 5 minutes. The sodium carbonate solution (75 g L\(^{-1}\), 2 mL) was added to the mixture and shaken. After 2 h at reaction at room temperature, the absorbance of blue coloration was measured at 760 nm. Gallic acid was used as the standard and the results were expressed as mg gallic acid equivalents (GAE) L\(^{-1}\).

Determination of flavonoids content (TFC)
TFC was assessed spectrophotometrically according to a previously published method with some modifications (Zhishen et al., 1999). The volume of 2.5 mL of extracts was mixed with 150 μL 5% NaNO\(_2\) solution and allowed to react during 6 minutes. 10% AlCl\(_3\) (150 μL) was added and left to react for 5 minutes. Afterwards, 1 mL of 1 mol L\(^{-1}\) NaOH solution and 1.2 mL of distilled water were added and absorbance was measured at 510 nm. Quercetin was used as the standard and the results were expressed as mg quercetin equivalents (QE) L\(^{-1}\).

Determination of flavan-3-ols content
The content of flavan-3-ols was estimated using the vanillin assay (Di Stefano et al., 1989). 500 μL of each extract was mixed with 3 mL of 4% vanillin solution and allowed to react for 5 minutes. 35% chloric acid (1.5 mL) was added to mixture and vigorously shaken. After 15 minutes of reaction at room temperature in dark, the absorbance of red coloration was measured at 500 nm. The amount of flavan-3-ols was calculated according to the corresponding formula based on difference between absorbance of vanillin-containing sample and blank. The results were expressed as mg (+)-catechin equivalents (CE) L\(^{-1}\).

Determination of DPPH radical-scavenging activity
The samples were analysed according to the slightly modified previously published procedure (Sharma, Bhat, 2009). An aliquot of each extract (0.2 mL) was mixed with 2.8 mL of DPPH (2,2-diphenyl-1-picrylhydrazyl) solution (mixture of 1.86×10\(^{-4}\) mol L\(^{-1}\) DPPH in ethanol and 0.1 mol L\(^{-1}\) acetate buffer (pH 4.3) in volume ratio 2:1). Free radical scavenging activity was determined by measuring the absorbance of solution at 525 nm after 30 minutes of reaction at room temperature in dark. Trolox was used as standard and the results were expressed as mmol Trolox equivalents (TE) L\(^{-1}\).

Determination of ferric reducing/antioxidant power (FRAP assay)
The FRAP assay was carried out according to the published procedure with some modifications (Benzie, Strain, 1996). The FRAP solution was prepared by mixing acetic buffer (pH 3.6), TPTZ (2,4,6-tri(2-pyridyl)-s-triazine) (10 mmol L\(^{-1}\)), ABTS (2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid)), potassium persulfate, sodium hydroxide, quercetin and vanillin were provided by Aldrich (Sigma-Aldrich Chemie Steinheim, Germany). Ethanol was procured from Vrenje Spiritana (Belgrade, Serbia).

Blackberry leaves (Čačanska Bestrna variety) were collected in Arilje (Western Serbia) during the full ripening stage of the fruits (July, 2015). Fully ripened blackberry leaves were healthy, uniform in the size and at the same senescence stage.

Harvested leaves were air-dried at room temperature in dark. Moisture content was determined (92.3%) according to a method approved by AOAC (Association of Official Analytical Chemists) International (AOAC, 1997). Afterwards, the dried material was ground in a laboratory mill to fine powder.

The aqueous extraction procedure was applied. The blackberry leaves (0.5 g) were extracted in 50 mL of distilled water on a magnetic stirrer. The effect of different extraction conditions: water temperature (40 and 80 °C) and extraction time (15 and 30 min) on the content of phenolic compounds, as well as antioxidant activity of extracts was studied. After extraction, the samples were centrifuged (centrifuge model: Boeco U-320 Hamburg, Germany) at 6000 rpm during 4 minutes.

Determination of total phenolic content (TPC)
TPC was determined according to a method with Folin-Ciocalteu's reagent (Singleton, Rossi, 1965). An aliquot of each extract (0.5 mL) was mixed with 10-fold diluted Folin-Ciocalteu's phenol reagent (2.5 mL) and allowed to react for 5 minutes. The sodium carbonate solution (75 g L\(^{-1}\), 2 mL) was added to the mixture and shaken. After 2 h at reaction at room temperature, the absorbance of blue coloration was measured at 760 nm. Gallic acid was used as the standard and the results were expressed as mg gallic acid equivalents (GAE) L\(^{-1}\).

Determination of flavonoids content (TFC)
TFC was assessed spectrophotometrically according to a previously published method with some modifications (Zhishen et al., 1999). The volume of 2.5 mL of extracts was mixed with 150 μL 5% NaNO\(_2\) solution and allowed to react during 6 minutes. 10% AlCl\(_3\) (150 μL) was added and left to react for 5 minutes. Afterwards, 1 mL of 1 mol L\(^{-1}\) NaOH solution and 1.2 mL of distilled water were added and absorbance was measured at 510 nm. Quercetin was used as the standard and the results were expressed as mg quercetin equivalents (QE) L\(^{-1}\).
The results of this study point out that blackberry leaves extracts are a source of total flavonoids and flavan-3-ols. Content of total flavonoids was significantly increased in the extract produced in water at 80 °C during 30 min. In the extracts prepared using water at higher temperature significantly higher content of flavan-3-ols was determined, while extraction time did not have statistically significant influence on the content of those compounds.

Generally, the chemical properties of extracts depend on the solvent type, the applied temperature and time, as well as the extraction technique (Ong, 2004). According to the results of this study, the extraction conditions have to be chosen concerning the phenolic class of interest.

The values of antioxidant activity of the blackberry leaves extracts determined by different methods are shown in Table 2. All analysed extracts expressed good ferric reducing / antioxidant power and DPPH radical scavenging activity, but weak ABTS radical scavenging activity. It has been reported that various methods for evaluation of antioxidant activity could give widely divergent results since they are based on different mechanisms (Tabart et al., 2009).

DPPH radical scavenging ability was a significantly lower in the extract prepared in the water heated to 40 °C during 15 min compared to the other extracts. Significantly stronger ferric reducing / antioxidant power was determined in the extracts prepared using water heated to 80 °C. At this temperature the extraction time had no a significant influence on antioxidant activity determined by FRAP assay. Therefore, the results point out to fluctuations in the antioxidant activity of all prepared extracts depending on the extraction conditions and applied assay. The results published by Wang, Lin (2000) indicated that leaf age could affect the antioxidant activity. It was also found that *Rubus* L. leaves have high antioxidant capacity and total phenolic content compared to their fruit tissues (Wang, Lin, 2000).

Significant positive correlations were found between the results of antioxidant activity (DPPH radical scavenging activity and ferric reducing / antioxidant power) and total flavonoids (Pearson correlation = 0.8171 and 0.8981, respectively). Study published by Oszmiański et al. (2015) showed that phenolic compounds of high molecular weight, primarily ellagitannins, are major contributors to antioxidant activity in leaves of Rubus L. species. According to the results of this study investigated conditions are suitable for production of extracts with high content of phenolic antioxidants. Using water as a solvent is acceptable since aqueous extraction simulates tea production and there is no need for evaporation and removing of potentially harmful solvents. Further research is needed in order to evaluate the effect of extraction conditions on the qualitative and quantitative composition of bioactive compounds.

Conclusions
The different extraction conditions (water temperature: 40 and 80 °C and extraction time: 15 and 30 min) were compared on the basis of the content of phenolic compounds and antioxidant activity of blackberry leaves aqueous extracts. This study indicates that blackberry leaves extracts are the rich source of phenolic antioxidants. The highest phenolic content and antioxidant activity were obtained in the extract prepared using water at higher temperature during prolonged time. Among investigated conditions, the use of water heated to higher temperature (80 °C) during prolonged time (30 min) is the most optimal procedure for the extraction of phenolic compounds with antioxidant activity from blackberry leaves. It is very important to determine the content and pharmacological properties of each phenolic compound in the prepared extracts since individual compounds have different antioxidant and health properties. Therefore, further research is needed to determine the exact phenolic profile, their bioavailability and health benefits of the extracts. Also, protective mechanisms should be investigated in order to maintain those compounds active during food processing and storage and enable their delivery to the target site in an organism.
